

Name: Sembrer, Christian Dane D.	Date Performed: 10/03/2025
Course/Section: CPE 212-CPE31S2	Date Submitted: 10/03/2025
Instructor: Engr. Robin Valenzuela	Semester and SY: 2025-2026
Activity 6: Targeting Specific Nodes and Managing Services	
<p>1. Objectives:</p> <ul style="list-style-type: none"> 1.1 Individualize hosts 1.2 Apply tags in selecting plays to run 1.3 Managing Services from remote servers using playbooks 	
<p>2. Discussion:</p> <p>In this activity, we try to individualize hosts. For example, we don't want apache on all our servers, or maybe only one of our servers is a web server, or maybe we have different servers like database or file servers running different things on different categories of servers and that is what we are going to take a look at in this activity.</p> <p>We also try to manage services that do not automatically run using the automations in playbook. For example, when we install web servers or httpd for CentOS, we notice that the service did not start automatically.</p> <p>Requirement:</p> <p>In this activity, you will need to create another Ubuntu VM and name it Server 3. Likewise, you need to activate the second adapter to a host-only adapter after the installations. Take note of the IP address of the Server 3. Make sure to use the command <i>ssh-copy-id</i> to copy the public key to Server 3. Verify if you can successfully SSH to Server 3.</p>	
Task 1: Targeting Specific Nodes	
<ul style="list-style-type: none"> 1. Create a new playbook and named it site.yml. Follow the commands as shown in the image below. Make sure to save the file and exit. 	

```

- --
- hosts: all
  become: true
  tasks:

    - name: install apache and php for Ubuntu servers
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
        update_cache: yes
        when: ansible_distribution == "Ubuntu"

    - name: install apache and php for CentOS servers
      dnf:
        name:
          - httpd
          - php
        state: latest
        when: ansible_distribution == "CentOS"

```

```

GNU nano 2.9.3      site.yml
- --
- hosts: all
  become: true
  tasks:

    - name: install apache and php for Ubuntu servers
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
        update_cache: yes
        when: ansible_distribution is defined and ansible_distribution == "Ubuntu"

    - name: install apache and php for CentOS servers
      apt:
        name:
          - httpd
          - php
        state: latest
        when: ansible_distribution is defined and ansible_distribution == "CentOS"

```

Read 22 lines

2. Edit the inventory file. Remove the variables we put in our last activity and group according to the image shown below:

```
[web_servers]
192.168.56.120
192.168.56.121

[db_servers]
192.168.56.122

[file_servers]
192.168.56.123
```

```
[ubuntu_servers]
$vbosuser/.ssh/id_rsa
192.168.56.110 ansible_user=vboxuser ansible_ssh_private_key_file=/home/vboxus$

[centos_server]
192.168.56.112 ansible_user=semlbrero ansible_ssh_private_key_file=/home/vboxus$

[workstation]
192.168.56.111 ansible_user=vboxuser ansible_ssh_private_key_file=/home/vboxus$
```

Make sure to save the file and exit.

Right now, we have created groups in our inventory file and put each server in its own group. In other cases, you can have a server be a member of multiple groups, for example you have a test server that is also a web server.

```
vboxuser@Workstation:~/CPE212semlbrero6$ ansible-playbook --ask-become-pass site
.yml
SUDO password:

PLAY [all] *****
*

TASK [Gathering Facts] *****
*

vboxuser@Workstation:~/CPE212semlbrero6$

```

3. Edit the *site.yml* by following the image below:

```

- hosts: all
  become: true
  pre_tasks:
    - name: install updates (CentOS)
      dnf:
        update_only: yes
        update_cache: yes
        when: ansible_distribution == "CentOS"
    - name: install updates (Ubuntu)
      apt:
        upgrade: dist
        update_cache: yes
        when: ansible_distribution == "Ubuntu"

- hosts: web_servers
  become: true
  tasks:
    - name: install apache and php for Ubuntu servers
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
        when: ansible_distribution == "Ubuntu"
    - name: install apache and php for CentOS servers
      dnf:
        name:
          - httpd
          - php
        state: latest
        when: ansible_distribution == "CentOS"

```

```

- - -
- hosts: all
  become: true
  pre_tasks:

    - name: install updates (CentOS)
      dnf:
        update_only: yes
        update_cache: yes
        when: ansible_distribution is defined and ansible_distribution == "CentOS"

    - name: install updates (Ubuntu)
      apt:
        upgrade: dist
        update_cache: yes
        when: ansible_distribution is defined and ansible_distribution == "Ubuntu"

- hosts: all
  become: true
  tasks:

    - name: install apache and php for Ubuntu servers

```

Make sure to save the file and exit.

The *pre-tasks* command tells the ansible to run it before any other thing. In the *pre-tasks*, CentOS will install updates while Ubuntu will upgrade its distribution package. This will run before running the second play, which is targeted at *web_servers*. In the second play, apache and php will be installed on both Ubuntu servers and CentOS servers.

Run the *site.yml* file and describe the result.

```

TASK [Gathering Facts] *****
*
ok: [192.168.56.109]
ok: [192.168.56.110]

192.168.56.112      : ok=2    changed=0    unreachable=0    failed=0

```

4. Let's try to edit again the *site.yml* file. This time, we are going to add plays targeting the other servers. This time we target the *db_servers* by adding it on the current *site.yml*. Below is an example: (Note add this at the end of the playbooks from task 1.3.

```

- hosts: db_servers
  become: true
  tasks:

    - name: install mariadb package (CentOS)
      yum:
        name: mariadb-server
        state: latest
        when: ansible_distribution == "CentOS"

    - name: "Mariadb- Restarting/Enabling"
      service:
        name: mariadb
        state: restarted
        enabled: true

    - name: install mariadb package (Ubuntu)
      apt:
        name: mariadb-server
        state: latest
        when: ansible_distribution == "Ubuntu"

```

```

- hosts: centos_server
  become: true
  tasks:

    - name: install mariadb package (CentOS)
      yum:
        name: mariadb-server
        state: latest
        when: ansible_distribution is defined and ansible_distribution == "CentOS"

    - name: "Mariadb - Restarting/Enabling"
      service:
        name: mariadb
        state: restarted
        enabled: yes

    - name: install mariadb package (Ubuntu)
      apt:
        name: mariadb-server
        state: latest

```

Make sure to save the file and exit.

Run the *site.yml* file and describe the result.

```

PLAY [centos_server] *****
*
TASK [Gathering Facts] *****
*
[WARNING]: Module invocation had junk after the JSON data:
AttributeError("module 'platform' has no attribute 'dist'")

ok: [192.168.56.112]

TASK [install mariadb package (CentOS)] *****
*
skipping: [192.168.56.112]

TASK [Mariadb - Restarting/Enabling] *****
*
changed: [192.168.56.112]

TASK [install mariadb package (Ubuntu)] *****
*
skipping: [192.168.56.112]
to retry, use: --limit @/home/vboxuser/CPE212semlbrero6/site.retry

PLAY RECAP *****
192.168.56.109      : ok=4    changed=0    unreachable=0    failed=0
192.168.56.110      : ok=4    changed=0    unreachable=0    failed=0
192.168.56.111      : ok=0    changed=0    unreachable=1    failed=0
192.168.56.112      : ok=4    changed=1    unreachable=0    failed=0

```

5. Go to the remote server (Ubuntu) terminal that belongs to the `db_servers` group and check the status for mariadb installation using the command: `systemctl status mariadb`. Do this on the CentOS server also.

Describe the output.

```

[semlbrero@localhost ~]$ systemctl status mariadb
Failed to execute 'pager', will try 'less' next: Permission denied
● mariadb.service - MariaDB 10.5 database server
   Loaded: loaded (/usr/lib/systemd/system/mariadb.service; enabled; preset: disabled)
   Active: active (running) since Fri 2025-10-03 18:48:57 PST; 47s ago
     Docs: man:mariadb(8)
           https://mariadb.com/kb/en/library/systemd/

            └─22246 /usr/libexec/mariabdb --basedir=/usr

lines 1-15/15 (FNN)

```

6. Edit the `site.yml` again. This time we will append the code to configure installation on the `file_servers` group. We can add the following on our file.

```
- hosts: file_servers
  become: true
  tasks:

  - name: install samba package
    package:
      name: samba
      state: latest
```

```
GNU nano 2.9.3      site.yml      Modified

- name: "Mariadb - Restarting/Enabling"
  service:
    name: mariadb
    state: restarted
    enabled: yes

- name: install mariadb package (Ubuntu)
  apt:
    name: mariadb-server
    state: latest
    when: ansible_distribution is defined and ansible_distribution == "Ubuntu"

- hosts: ubuntu_servers
  become: true
  tasks:

  - name: install samba package
    package:
      name: samba
      state: latest
```

Make sure to save the file and exit.

Run the *site.yml* file and describe the result.

```

```

The testing of the *file_servers* is beyond the scope of this activity, and as well as our topics and objectives. However, in this activity we were able to show that we can target hosts or servers using grouping in ansible playbooks.

Task 2: Using Tags in running playbooks

In this task, our goal is to add metadata to our plays so that we can only run the plays that we want to run, and not all the plays in our playbook.

1. Edit the *site.yml* file. Add tags to the playbook. After the name, we can place the tags: *name_of_tag*. This is an arbitrary command, which means you can use any name for a tag.

```

---
- hosts: all
  become: true
  pre_tasks:

    - name: install updates (CentOS)
      tags: always
      dnf:
        update_only: yes
        update_cache: yes
        when: ansible_distribution == "CentOS"

    - name: install updates (Ubuntu)
      tags: always
      apt:
        upgrade: dist
        update_cache: yes
        when: ansible_distribution == "Ubuntu"

```

```

- hosts: web_servers
  become: true
  tasks:

    - name: install apache and php for Ubuntu servers
      tags: apache,apache2,ubuntu
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest

```

Task 3: Managing Services

1. Edit the file site.yml and add a play that will automatically start the httpd on CentOS server.

```
- name: install apache and php for CentOS servers
  tags: apache,centos,httpd
  dnf:
    name:
      - httpd
      - php
    state: latest
    when: ansible_distribution == "CentOS"

- name: start httpd (CentOS)
  tags: apache, centos,httpd
  service:
    name: httpd
    state: started
    when: ansible_distribution == "CentOS"
```

Figure 3.1.1

```
dnf:
  name:
    - httpd
    - php
  state: latest
  when: ansible_distribution is defined and ansible_distribution == "CentOS"

- name: start httpd (CentOS)
  tags: apache, centos, http
  service:
    name: httpd
    state: started
  when: ansible_distribution is defined and ansible_distribution == "CentOS"
```

Make sure to save the file and exit.

You would also notice from our previous activity that we already created a module that runs a service.

```
- hosts: db_servers
  become: true
  tasks:

    - name: install mariadb package (CentOS)
      tags: centos, db, mariadb
      dnf:
        name: mariadb-server
        state: latest
        when: ansible_distribution == "CentOS"

    - name: "Mariadb- Restarting/Enabling"
      service:
        name: mariadb
        state: restarted
        enabled: true
```

Figure 3.1.2

This is because in CentOS, installed packages' services are not run automatically. Thus, we need to create the module to run it automatically.

2. To test it, before you run the saved playbook, go to the CentOS server and stop the currently running httpd using the command *sudo systemctl stop httpd*. When prompted, enter the sudo password. After that, open the browser and enter the CentOS server's IP address. You should not be getting a display because we stopped the httpd service already.

3. Go to the local machine and this time, run the *site.yml* file. Then after running the file, go again to the CentOS server and enter its IP address on the browser. Describe the result.

To automatically enable the service every time we run the playbook, use the command *enabled: true* similar to Figure 7.1.2 and save the playbook.

Reflections:

Answer the following:

1. What is the importance of putting our remote servers into groups?

Remote servers are significantly easier to manage when grouped together. You can apply the same actions to a number of servers at once rather than setting or updating each one individually.

2. What is the importance of tags in playbooks?

Tags enable us to execute only particular sections of a playbook without having to walk through the everything.

3. Why do think some services need to be managed automatically in playbooks?

Certain services must always be operational because they are essential.

Using playbooks to manage them automatically guarantees that they always start up correctly, restart when necessary, and are configured correctly. Instead of depending on someone to complete it manually each time, this helps prevent downtime and keeps everything operating properly.
